

Shattermancer Battle2 Deployment Diagnosis

Cloudflare / Static Asset Inclusion Investigation for Claude

Purpose: Use this as the authoritative diagnosis brief for the current live-build failure. The evidence isolates the issue to deployment/static asset inclusion for the new assets/battle2/ directory.

Confirmed facts

- assets/battle2/ exists in the actual Shattermancer production repo.
- It is in the correct location.
- The 17 files are committed and pushed.
- The intended branch is being used.
- index.html is already byte-identical to the validated Battle vNext build and should remain untouched.
- The Battle vNext runtime/DOM is clearly present in the live build.
- The new assets.json registrations are active enough that the live screen is attempting to use the Battle vNext asset layer.
- Direct URLs to multiple files under assets/battle2/ fail in Safari with a broken-image page.
- A direct URL to a known existing image under assets/battle/ loads correctly.

Live screenshot evidence

- Runtime text/content still appears: enemy/player names, HP values/fills, ATTACK text, element artwork/names/mana, Grimoire blank-state text, and the legend ?.
- New Battle2 painted assets are missing: scene backdrop, enemyPanel, playerPanel, intent ribbon, book, draftArea, slot, waxSeal, lowerUI, rune frames, potionSlot frames, CAST, and spell frames.
- This pattern is consistent with the correct Battle vNext implementation running while assets/battle2/*.webp files are not being served.

Direct URL test results

- Tested deployed URLs including assets/battle2/book.webp, assets/battle2/sceneArt_act1.webp, assets/battle2/enemyPanel.webp, assets/battle2/lowerUI.webp, and assets/battle2/cast.webp.
- Every one fails with a broken-image page.
- A known-good URL under assets/battle/... loads normally.
- Therefore treat this as a directory-level deployment inclusion/serving problem for assets/battle2/.

Do not change

- index.html
- CSS
- geometry
- artwork
- the 17 asset bytes
- Battle vNext runtime layout
- title/shield placement
- any pending utility art
- Do not assume this is a browser-cache issue unless you can prove it.

Diagnose only the deployment layer

- Determine the exact reason assets/battle/... is deployed and served correctly while assets/battle2/... is not.
- Check whether Cloudflare deployed the latest commit containing assets/battle2/.

- Check whether the deploy/build process copies or includes only known/pre-existing asset directories.
- Check for an asset-directory allowlist or glob pattern that includes battle/ but not battle2/.
- Check whether a generated static asset manifest needs to be rebuilt.
- Check whether Wrangler/static asset configuration excludes or fails to discover the new directory.
- Check whether the deployment root/output directory contains assets/battle/ but omits assets/battle2/.
- Check whether any build script explicitly enumerates asset folders.
- Check whether .gitignore, deployment ignore rules, or copy rules affect the new folder.
- Check whether a Worker route or fallback handler intercepts assets/battle2/*.
- Check whether the deployed Worker/site build is based on a stale output tree despite the repo being current.

Inspect these Shattermancer deployment files/configs where applicable

- wrangler.toml
- wrangler.json
- wrangler.jsonc
- worker entry file
- package scripts
- build scripts
- deploy scripts
- copy scripts
- generated asset manifests
- static asset configuration
- route/fallback logic

Required response

1. Exact deployment mechanism currently used.
2. Exact reason assets/battle2/ is omitted or not served while assets/battle/ works.
3. Narrowest proposed fix.
4. Whether that fix requires a new deployment.
5. Whether any config/build artifact must be regenerated.
6. One representative direct URL that should load successfully after the fix.
7. Any verification step I should perform after redeploying.

STOP CONDITION

Do not apply broad changes. Do not touch runtime UI code or artwork. Stop after identifying the exact deployment-layer cause and proposed narrow fix.
